

# THE BENEFITS OF GEOGRAPHIC NAMES TO A SPATIAL DATA INFRASTRUCTURE AND TO A NATION

*Prof. John PARKER, Chair of FIG Commission 1, Australia*

**Key words:** Spatial data infrastructure, geographic names, standardisation, consistent, national, regional.

## INTRODUCTION

In many countries the concept of national infrastructures is not new. In many nations, the major road and telecommunications networks, and basic health and education facilities, have been funded by government to ensure that consistent infrastructure is developed in the national interest. The rationale is that a legitimate role of government, on behalf of the community, is to provide a common, consistent infrastructure upon which a variety of government, private sector and community activities can take place.

Land and geographic information can be viewed as an infrastructure, with the same rationale and characteristics as roads, communications and other infrastructure.

Geospatial Information (GI), has been collected and managed mainly in the form of maps and text, the advent of digital data has created a change in the way we think about and want to use GI. These new possibilities are the impetus behind the conceptualisation and development of a system of integrated data sets, which are independent of, and integrate the data of the separate administrative and political jurisdictions of a country or a region.

It is important to note that micro-economic reforms and structural adjustment, such as competition policy, streamlining government business and focussing on core roles of government, have reinforced for all governments the need to develop a single integrated, easily accessible land information infrastructure. Many of the key land information projects in the planning or early implementation stage at the moment, require levels of investment, which emphasise the need for all jurisdictions to operate nationally and regionally to meet national and regional needs. Only a national system, a national market can maximise the investment required in data collection and maintenance.

## NATIONAL/REGIONAL SPATIAL DATA INFRASTRUCTURE

Geographic (or spatial) data describes information that can be related to a position on the earth's surface whether that is on the land, sea or in the air. Information about geographic names, vegetation, minerals, road networks, property ownership, soils, air quality and population distribution can all be spatially related. National/Regional issues such as catchment management, land development and transport planning all require good,

International Conference on Spatial Information for Sustainable Development  
Nairobi, Kenya  
2-5 October, 2001

consistent spatial information. There are few areas of cooperation within or between nations, which do not rely either directly or indirectly on this kind of information.

In some parts of the world National Spatial Data Infrastructures (NSDI) and/or Regional Spatial Data Infrastructures (RSDI) are being developed, for example, the Asia-Pacific Spatial Data Infrastructure (APSDI) proposed by the Permanent Committee on GIS Infrastructure for Asia and the Pacific (PCGIAP) has the following objectives (as set out in Article 5 of the Statutes) which it is endeavouring to achieve:

- a. To define the nature of a regional geographic information infrastructure that each country in the region can contribute to in order to meet regional and global mapping and GIS requirements.
- b. To determine the nature of legislative and administrative procedures and orders appropriate to the acquisition and sharing of spatial data.
- c. To develop a regional geodetic framework, regional topographic datasets, national cadastral datasets and regional **geographical names** datasets as the basis for regional GIS activity.
- d. To document the status of key geographic datasets and key agencies in each member nation, and develop a framework for the exchange of such information.
- e. To prepare guidelines and strategies to assist member nations for the implementation of cadastral development to meet individual member nation needs.
- f. To determine the need for research, training and technology and policy exchange in relation to the beneficial impact of geographic information on the social, economic and environmental objectives of member nations of Asia and the Pacific region.
- g. To explore opportunities for aid funding to support development needs of member nations and for the development of a regional spatial data infrastructure.

The PCGIAP's vision for the Asia-Pacific Spatial Data Infrastructure (APSDI) is of a network of databases, located throughout the region, that together provide the fundamental data needed to achieve the region's economic, social, human resources development and environmental objectives.

Those distributed databases include geodetic, topographic, hydrographic, geographic names, administrative and environmental data. They may, in the future, be linked electronically so that they appear, to the user, as a virtual database, but they will also be linked together in a number of other important ways:

- they will be linked by an intra-regional institutional framework that provides mechanisms for sharing experience, technology transfer and coordination of the development of the regional fundamental datasets.

---

TS1.3 Prof. John Parker: The Benefits of Geographic Names to a Spatial Data Infrastructure and to a Nation

- they will be linked by the use of common technical standards, including a common geodetic reference frame, so that data from numerous databases can be brought together to create new products and solve new problems, both regionally and globally;
- they will be linked by the adoption of common policies on data access, pricing, privacy, confidentiality and custodianships, they will be linked by the implementation of inter-governmental agreements on data sharing;
- they will be linked through a comprehensive and freely accessible directory of available datasets containing descriptions and administrative information that accords with agreed standards for meta data;

It is this suite of administrative and technical linkages that distinguishes a NSDI or RSDI from a collection of uncoordinated datasets, which will make it such a powerful tool for a nation's or region's economic and social development.

I am sure this conference believes that resources should not be wasted on duplicated effort. I am confident that there are many in the African continent who believe that the nations of the region should reach agreement on what fundamental datasets are required to meet their common interests, to what standards they should be collected and maintained, which agencies should have custodianship of those data, and what the priorities are for their collection.

A NSRI or RSDI can provide the institutional and technical framework to ensure the required consistency, content and coverage to meet regional needs. The infrastructure also ensures that national efforts are focussed and coordinated, thereby maximising investment in data collection and maintenance from a regional perspective. Finally, such an infrastructure will help achieve better outcomes for the region through better support for economic, social and environmental decision making.

In Australia and New Zealand, the Australian and New Zealand Land Information Council (ANZLIC) and in the Asia Pacific area the Permanent Committee on GIS Infrastructure for Asia and the Pacific (PCGIAP) have developed a spatial data infrastructure model that comprises four core components – institutional framework, technical standards, fundamental datasets, and access networks. These core components are linked as follows:

### **Institutional Framework**

Defines the policy and administrative arrangements for building, maintaining, accessing and applying the standards and datasets

### **Technical Standards**

Define the technical characteristics of the fundamental datasets and enable them to be integrated with other environmental, social and economic datasets.

## **Fundamental Datasets**

Are produced within the institutional framework and fully comply with the technical standards

## **Access Network**

Is the means by which the national or regional fundamental datasets are made accessible to the community, in accordance with policy determined within the institutional framework, and to the technical standards agreed.

The essential component of a NSDI or RSDI are the Fundamental Datasets which are produced within the Institutional Framework and are collected as primary data sources, from which other data and information are derived by integration or value-adding. A fundamental dataset is defined as follows:

A fundamental dataset, in the context of a National or Regional Spatial Data Infrastructure, is a dataset for which there is a demand for consistent national or regional coverage. This demand for a consistent coverage implies that:

- there is a need for coordination between custodians to ensure that components of that region datasets are collected to consistent standards;
- the community of users must be adequately consulted to determine specifications and priorities;
- access to the data is provided in accordance with policies determined for a National or Regional Spatial Data Infrastructure; and
- the national or regional datasets conforms to a set of standards that ensures that it can be combined with other components of a National or Regional Spatial Data Infrastructure to create value added products.

There are three principal issues associated with the provision of national or regional fundamental datasets:

- identification and prioritisation;
- production and integration; and
- data maintenance.

I believe geographic names is a fundamental data set for any nation or region.

## **GEOGRAPHIC PLACE NAMES**

Place names are perhaps the most commonly and widely used form of geospatial information, consisting of official and local names of administrative, cultural and geographic features, including streets and roads. Each individual toponym (name) constitutes a relatively simple datum, but with growing community demands, and

---

TS1.3 Prof. John Parker: The Benefits of Geographic Names to a Spatial Data Infrastructure and to a Nation

sophisticated advances in technology, place names are now required to meet many levels of service expectation, where the currency of data is of key importance.

Foremost is the demand for real time data, in the protection of life and property by emergency service organisations. At a more general level, current data on location and extent is required by a wide range of administrative and planning agencies, such as statistics for population and census planning and development programs. At another level again, there is a growing demand for, and expectation of, access to the historical data inherent in the record of successively assigned place names and their “meaning”.

The role of geographic names is superficially, pretty self-evident. Though there are aspects of the need to regulate/standardise the use, collection, and registration of place names for official purposes, which are not so readily apparent.

The naming of places and geographic features is a very human activity, springing in the first instance from a need to know and relate to landscape. The mass movements of peoples, in the last several centuries, and nostalgia for “home” places, has uniquely marked the geography and history of the landscape.

There are two main areas in which the community as a whole, has an interest in the naming of places:

1. Ensuring the capacity to unambiguously identify and locate geographical entities and places, as an essential reference system for services, infrastructure and public administration.
2. Ensuring that the valuable record of a country’s place names, with its variety of sources, reflecting unique patterns of settlement is preserved and accessible.

Given these public interest objectives, governments in many countries have established Geographic Names Authorities, whose central role is to authorise place names for official purposes and to issue policy guidelines on standard usage, and written form and spelling.

Government’s primary role in standardisation and registration is to promote effective, useable place names, to provide unambiguous direction. While this is obvious, there are many ways in which clear identification and unambiguous use are compromised.

- Many places have more than one name
- Many names are duplicated even in local areas
- Names may have variant spelling
- Local names may be different to the more widely recognised international names
- Names in some countries can be written in non-Roman script.

A secondary purpose, shared by a range of interested groups and organisations – is the collection and preservation of place and feature names, and their variants over time, as they

retain much of our culture memory and heritage. Place names are often an important contributor to historical information.

## **UNITED NATIONS GROUP OF EXPERTS ON GEOGRAPHICAL NAMES (UNGEGN)**

Consistent use of accurate place names is an essential element of effective communication worldwide and supports social-economic development, conservation and national infrastructure. That is why the United Nations establish a Group of Experts on Geographical Names.

UNGEGN is one of the seven standing expert bodies of the United Nations Economic and Social Council (ECOSOC). It was established in 1959, to promote the standardisation of place/feature names at both the national and international levels and is, by virtue of its composition and status, the most authoritative body dealing with geographic names. The outcomes of the work undertaken, are the resolutions adopted at UN Conferences and when implemented they ensure products and data which comply with the highest international standards.

UNGEGN acts as collegiate, consultative body and agreement is reached by consensus; decisions are recommendatory in character, and do not compromise national sovereignty as international standardisation is carried out on the basis of national standardisation. UNGEGN members bring to these issues the foremost developments in the science of language treatment and state of the art digital information management.

UNGEGN functions to develop procedures and mechanisms for standardisation in response to national needs, to develop programs of training, and particularly to assist countries which have not developed systems for the maintenance of consistent place names. Members address the outcomes and resolutions of previous United Nations Conferences on the Standardization of Geographical Names and undertake preparatory work for future international conferences and sessions of the Group of Experts.

The UN Conference promotes a formal naming process because of its importance in areas such as environmental management, sustainable development, search and rescue, peacekeeping and international aid operations, trade and commerce, population census, planning, property rights, tourism, cartography, communication and overall economic development and social welfare.

The application and spelling of names of cities, villages, land and water features must be clear, current, accurate, and unambiguous. Effective communication depends on appropriate use of these names on maps, in the media and in legal documents. Inaccuracy and misrepresentation can lead to inefficiency and loss of life.

A brochure recently produced by UNGEGN sets out how everyone benefits from a consistent naming process and some of the programmes it is involved in.

---

TS1.3 Prof. John Parker: The Benefits of Geographic Names to a Spatial Data Infrastructure and to a Nation

To support the work of UNGEGN and to provide a closer interface to nations, UNGEGN has a number of linguistic and geographical divisions. Within Africa there are a number of divisions including the Africa Central Division, Africa East Division, Africa South Division, Africa West Division, and Arabic Division.

## **GEOGRAPHIC NAMES AND A REGIONAL SPATIAL DATA INFRASTRUCTURE**

To inter-relate geographic names, the work of UNGEGN, its Divisions and a National or Regional Spatial Data Infrastructure (RSDI) the four core components of the Asia Pacific Spatial Data Infrastructure will be used.

### **Institutional Framework**

An opportunity exists for Regional organisations or Committees, e.g. UN ECA, through their working groups or sub-committees to take a leadership role in supporting and encouraging nations to develop a consistent or standardised approach to geographical naming. The regional organisations could act as sponsor of the geographical names dataset in conjunction with the UNGEGN Divisions to ensure that a names data set for the region is assembled, maintained, delivered and accessible in a consistent way. The institutional framework of UNGEGN and its Divisions would be able to support such initiatives. An important role of UNGEGN is to provide or encourage training for countries wishing to form national name authorities or to create a place names register.

### **Technical Standards**

The UNGEGN encourages all nations to develop toponymic guidelines for their country which not only supports standardisation within the country, but also allows other nations to understand the standardisation approach taken. Appendix 1 provides an outline of the key elements that should be considered in such guidelines.

Other key technical areas that UNGEGN undertakes a role in, is, supporting the development of single romanization systems, the development and promotion of standardised terminology in connection with place names and promoting the development of national automated data processing capabilities and international technology exchange.

This conference has the opportunity to assist UNGEGN in this work by encouraging nations to develop toponymic guidelines and national gazetteers that allow the formation of a Regional gazetteer/dataset if required.

### **Fundamental Datasets**

As noted above, geographic names is a fundamental dataset. Nations need to be supported and encouraged to establish an authority in each country for national names standardisation, with the resultant names register, providing the basis for a geographic names dataset for the region. It can draw attention to duplication of names or where more

---

TS1.3 Prof. John Parker: The Benefits of Geographic Names to a Spatial Data Infrastructure and to a Nation

than one name exists for the same place. To assist in the preparation of this dataset it can encourage collaboration between countries on the standardisation of names for trans boundary features.

### **Access Network**

Dissemination of standardised names is a key element of any naming process, not only in promoting the application of such names on maps and in documents but also in developing access to the national gazetteers through publication or through on-line processes. Regional organisations can play a positive role in working with nations within the region to facilitate the development of a technological framework that will provide the communities within the region access to this fundamental dataset.

### **OTHER GLOBAL PROGRAMS**

All of the above, needs to be considered in light of the global programs that exist, whether they be UNGEGN related, other Regional initiatives or such programs as the Global Map or the Global Spatial Data Infrastructure.

### **CONCLUSION**

As a fundamental data set of a NSDI or RSDI, it is of the utmost importance to develop appropriate relationships and processes between the critical providers of data at national level, and the data base custodians who determine technical standards for data, and protocols and procedures for the entry, accessing and use of data. It will be imperative, that these relationships are collaborative and driven by the needs and preferences of users and beneficiaries of the data; not by technical imperatives or primarily by the unilateral actions of data base custodians.

There is the opportunity for this conference to support the work of UNGEGN throughout the Region with the ultimate result of achieving a fundamental data set for a Spatial Data Infrastructure.

Geographic names are a vitally important part of geospatial information, and not in a technical sense alone. If you can, imagine for a moment, a world without 'names' for places or landscape features, it would be a very colourless world, and if you'll pardon the pun a 'flat' world indeed, and no doubt impossible to get around in. If it is, hard to envisage, it is because, as well as serving to identify location, and communication direction, place names also express tangibly the human activity of investing the landscape with meaning and memory.

If geographic names as a fundamental data set can create such benefits with a standardised and consistent approach, it can be imagined once integrated with other fundamental data sets into a Spatial Data Infrastructure, the benefits both economically and socially grow dramatically.

---

TS1.3 Prof. John Parker: The Benefits of Geographic Names to a Spatial Data Infrastructure and to a Nation

## BIOGRAPHICAL NOTES

Professor John Parker is an international land administration consultant specialising in quality management, professional practice and management and geographical names.

He was Surveyor General of Victoria in Australia for nine years and had spent nineteen years in private practice in a multi disciplinary firm. His responsibilities have included being the Registrar of Geographic Names in Victoria, Australia, the chair of the Committee for Geographic Names in Australasia, the chair of the United Nations Group of Experts on Geographical Names Asia, South East and Pacific, South West Division.

Currently he is actively involved in the International Federation of Surveyors and is chair of FIG Commission 1 (Professional Standards and Practice). Membership of professional associations includes the Institution of Surveyors Australia. Papers have been presented and published at a range of events, including international forums, on a wide range of subjects.

## **APPENDIX 1: TOPONYMIC GUIDELINES,**

As originally proposed by Dr. Josef Breu in his Circular No. 2, 12 December 1977, with additions, modifications and new numbering of 1981 (Circular Letter No. 20). The title reflects modifications from the Eighth Session of UNGEGN, 1979 and from the Fourth Conference, 1982. Item 6 follows a resolution of the Fifth Conference, 1987.

### **Toponymic Guidelines for Map and Other Editors, for International Use**

Name of individual country

1. Languages
  - 1.1 General remarks
  - 1.2 National language(s)
    - 1.2.1 Legal situation and practical application in administration and official cartography
    - 1.2.2 Alphabet(s) and transcription(s)
    - 1.2.3 General spelling rules for geographical names
    - 1.2.4 Pronunciation
    - 1.2.5 Grammatical peculiarities which are essential for the treatment and understanding of geographical names
    - 1.2.6 Distribution of main dialects and their characteristics; how far are dialectal name forms adapted to the standard form of the language(s)? (In the case of many African countries with English, French, Portuguese or Spanish as official languages: Distribution of main vernaculars and their characteristics; how far are vernacular name forms adapted to the spelling of the official language?); linguistic maps
  - 1.3 Minority languages
    - 1.3.1 - 1.3.6, as under 1.2
2. Names authorities and names standardization
  - 2.1 National names authority. Aims, functions, rules, address.
  - 2.2 Provincial names authorities. Aims, functions, rules, addresses.
  - 2.3 Names standardization. Legal aspects, procedures, progress.
3. Source Material
  - 3.1 Maps: map series containing standardized names. Which sheets of a series contain already standardized names?
  - 3.2 Gazetteers containing standardized names.
4. Glossary of appellatives, adjectives and other words necessary for the understanding of maps (As such glossaries will serve the needs of foreign users they must contain also – and above all – words of the general vocabulary.)
5. Abbreviations used on official maps; the decoding and meanings
